

Vector Databases

A vector database is a specialized data store designed to hold high-dimensional numerical vectors, typically produced by embedding models. Instead of searching by exact keyword match, a vector database finds the nearest neighbors to a query vector using distance metrics such as cosine similarity or Euclidean distance.

This project uses ChromaDB as its vector database. ChromaDB persists its data to a local folder called `chroma_db`, and supports adding, querying, and deleting vectors by metadata filters, which is essential for keeping search results in sync with documents that are added, deleted, or modified over time.
